Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

## Description

The invention relates to cast contact lenses and more particularly to apparatus and methods for producing and packaging such cast contact lenses.

Cast moulding is a known method for the production of contact lenses. It offers considerable quality and cost advantages over other methods such as lathing and/or spin-casting. It is a highly repeatable process.

During cast moulding it is important to maintain a good seal between the mould pieces in order to prevent the loss of volatile components from monomer used to make the lens and to provide a clean edge profile to the cast lens. Using existing methods the mould pieces are generally held together by mechanical means. However, during curing the mould pieces may relax resulting in uneven sealing loads. It is also difficult to design moulds where sufficient pressure is applied to the mould parts at the seal line between the mould parts so as to separate the monomer in the lens cavity from any excess monomer which is displaced into flash cavities. Imperfectly made seals result in damaged lenses and costly inspection is needed to separate reject from good lenses.

During cast moulding it is also important to compensate for monomer shrinkage which occurs during the polymerising curing process in order to prevent the formation of voids or bubbles in the lens due to cavitation effect. To reduce this problem existing methods are known which provide one of the mould pieces with a flexible rim which collapses during polymerisation. Other systems allow monomer from a reservoir cavity in the mould to flow back into the lens cavity due to suction effect of shrinkage and other systems allow the mould surfaces to move towards one another under suction effect. However, the flexible rim and reservoir methods disturb the seal and reject lenses or lenses requiring edge polishing result. An advantage of mould surface movement over other methods is that it does allow the seal line to be maintained intact but the mould shells must be carefully designed to collapse evenly under suction forces. Variations in mould thickness, material or cure temperature will affect mould stiffness and hence the rate and amount of collapse. The monomer shrinkage induced suction has to overcome the natural stiffness of the mould structure without for example sucking monomer in from a flash cavity around the mould. During cast moulding it is necessary to provide a cavity or cavities within the mould assembly to contain excess monomer squeezed out from the lens cavity as the mould pieces are brought together. This excess monomer forms flash during the curing process and this flash must be separated from the lens prior to packing. In

some cases the flash is preferentially fixed to one of the mould pieces by the provision of snatch rings but generally the separation process is carried out manually and is costly.

A known method of manufacturing contact lens is described in International patent application No WO87/04390. A two part mould is used of which one portion of the mould is flexible so that it moves under the suction generated by the monomer during polymerisation.

The preambles of claims 1 and 15 are based on this document.

In US3830460 a method and a mould for manufacturing ophthalmic lens for use for example in spectacles are described. The mould is in two parts, a female mould half and a male mould half, of which one of the halves has a flexible membrane to accommodate the shrinkage of the lens whilst curing. To assist in ensuring the flexure of the membrane the mould is exposed to a positive pressure during the curing of the lens. A shoulder on the male mould half has a flat surface which engages with a flange on the female mould surface, when in use, forming a circumferential seal about the mould cavity.

During cast moulding the lens will, after curing, tend to adhere to one or other of the mould pieces in a random manner unless the moulds are designed to hold the lens on one specific half. There are processing advantages in being able to control or define on which mould half the lens will be held when the mould pieces are separated after curing. Moulds which rely on flexible rims to compensate for monomer shrinkage will tend to retain the lens on the mould piece which has the rim. This is because the rim deflects generally into the lens cavity where the monomer hardens around it. While this process can, to some extent, be relied upon to fix the lens on one half, the net effect of the rim is to deform the edge of the lens resulting in inconsistent edge profiles, reject lenses and edge polishing even of the acceptable lenses i.e. those which have not been damaged by mechanical removal from the retaining mould half. Another method for retaining the lens on one specific mould piece is to create a return on the edge of the lens cavity in such a way as to wedge the hard lens. For example a lens cavity on the concave mould may have a returned edge profile which will retain the hard lens. Unfortunately this creates considerable constraints on the design of the lens edge profile and the creation of relatively thick uncomfortable lens edges.

During the process of cast moulding certain batches may require to be tinted or coloured. There are a number of tinting systems but they require the careful location and support of the lens such that ink or dye can be precisely applied to the

lens surface generally the front convex surface without damage to the lens. This positioning of the lens is a labour intensive operation requiring considerable operator skill if rejects are to be minimised.

During the process of cast moulding it may be desirable to carry out some form of work on the lens such as surface treatment. There are cost and quality advantages in carrying out these operations while the lens is still captive on one of the mould pieces but it is necessary to be able to guarantee on which mould half the lens is retained.

During the process of cast moulding the lens is handled in a number of different containers as it undergoes inspection, power measurement, extraction, hydration and transfer to the final pack, generally a glass vial. There can be cost and quality advantage if these operations can be carried out in the mould which is also a main component in the final pack. There are also advantages if the mould piece forming part of the pack is of such design that the lens is properly orientated and accessible for ease of removal by the user. This may be achieved by offering the lens with the convex surface uppermost. Alternatively there may be advantage in providing a "basket" or carrier device within the pack which contains the lens and which is accessible to the user thereby making lens removal from the pack easy.

During cast moulding it is extremely important to protect the optical surfaces of the mould pieces since the slightest damage mark will be transferred to the lens resulting in a reject. Damage can occur for example when the mould is ejected from the moulding machine. Similarly for hygiene reasons it is important to minimize the possibility of an optical surface coming into contact even with soft objects.

It is an object of the present invention to provide improved apparatus and methods for cast moulding contact lenses.

It is a further object of the present invention to provide an improved method and apparatus in which a sealing cover may be sealed over one of the mould halves to form a package.

The present invention provides a method of cast moulding a contact lens comprising the steps of:

filling with monomer a mould cavity of a mould, said cavity being between relatively movable male and female mould surfaces and said mould further comprising a rigid shoulder for forming a peripheral seal between the two mould surfaces to close the cavity, at least one of the mould surfaces but not the shoulder being flexible under a loading pressure;

closing said mould cavity with monomer filling said cavity;

curing the monomer while applying a sealing

pressure to provide a pressurized seal against the rigid shoulder and a loading pressure to cause deflection of one of the mould surfaces to maintain the mould surfaces in contact with the lens as the monomer shrinks during polymerisation, characterised in that a superatmospheric pressure in a pressure vessel is applied to said mould, said superatmospheric pressure providing both said loading pressure and said sealing pressure, and is sufficient to cause the said pressurised seal formed by the rigid shoulder to be maintained around the mould cavity throughout polymerisation to separate the contact lens from any flash, and the loading pressure to be sufficient to maintain the mould surfaces in contact with the lens as the monomer shrinks.

Preferably the male and female mould surfaces are formed on respective mould parts arranged to engage each other as a sliding piston and cylinder device, said application of the superatmospheric pressure being applied to both mould parts thereby urging the male and female mould surfaces towards each other.

Preferably monomer is fed to said mould cavity while the female mould surface is facing upwardly, and inverting the mould so that on opening the mould said male surface is facing upwardly.

In a further aspect, the present invention provides a moulding apparatus for use in a method as hereinbefore described which moulding apparatus comprises a mould, said mould having a first mould part having a male mould surface, a second mould part having a female mould surface and a rigid shoulder which forms a peripheral seal between the two mould surfaces under sealing pressure, each of said mould parts having a base on which the respective mould surface is formed and an annular wall extending upwardly from the base, the annular walls of the first and second mould parts being arranged to engage each other as a sliding fit whereby the two mould parts may be moved as a piston and cylinder device to open and close the mould, at least one of the mould surfaces but not the shoulder being flexible under a loading pressure, characterised in that the apparatus further comprises a pressure vessel in which said mould is received during the formation of a lens, said pressure vessel being arranged, in use, to apply superatmospheric pressure to said mould, said superatmospheric pressure providing both said loading pressure and said sealing pressure, and is sufficient to cause the said pressurised seal formed by the rigid shoulder to be maintained around the mould cavity throughout polymerisation to separate the contact lens from any flash, and the loading pressure to be sufficient to maintain the mould surfaces in contact with the lens as the monomer shrinks.

Preferably, the male mould surface is formed on the base of said first mould part spaced inwardly from the annular wall of the first mould part so as to provide a trough within the annular wall surrounding said male mould surface.

Furthermore, preferably the annular wall of said first mould part is formed with a flange at its upper end onto which a sealing cover may be sealed.

Attention is drawn to EP-A-0561480, a divisional application from the present application which describes and claims a method of cast moulding a contact lens comprising polymerising a monomer in a mould cavity between a male mould surface in a first mould part and a female mould surface in a second mould part, opening the mould to expose the cast lens while supported on said male mould surface, and sealing the lens in a package by sealing a cover member onto said first mould part.

Attention is also drawn to EP-A-0561481, a divisional application from the present application which describes and claims a method of cast moulding a contact lens comprising polymerising a monomer in a mould cavity between a male and female mould surface, opening the mould to expose the cast lens while supported on one of the mould surfaces, perforating the lens by application of a laser beam to provide a controlled porosity of the lens, applying a drug or other medication to the lens so that the dosage taken up by the lens is determined by the extent of porosity formed and the concentration of the drug or medication, and sealing the lens in a package by sealing a cover member onto the part of the mould supporting said lens.

Some embodiments of the invention will now be described by way of example and with reference to the accompanying drawings in which:

Figure 1 shows a cross-section of a mould assembly prior to location in a pressure vessel for use in accordance with the present invention,

Figure 2 shows an enlarged view of a seal between the two mould parts of the apparatus shown in Figure 1,

Figure 3 shows the mould assembly of Figure 1 when located in a pressure vessel,

Figure 4 shows a first part of the mould assembly of Figure 1 with a cast lens after inversion and the mould is opened,

Figure 5 shows a sealed package with a hydrated cast lens formed in accordance with the invention, and

Figures 6, 7 and 8 show alternative perforated lenses in accordance with the invention.

This example relates to the formation of a cast contact lens by polymerising a monomer in a mould cavity between a male mould surface in a first mould part and a female mould surface in a

second mould part. In the drawings the first mould part 11 comprises a cup member having a base 12 surrounded by an annular wall 13. The male mould surface 14 is formed centrally on the base 12 spaced away from the annular wall 13 so that an annular trough region 15 is formed between the annular wall 13 and the male mould surface 14. The second mould part 16 is also cup shaped in that it has a base 17 surrounded by an annular wall 18. The female mould surface 19 is formed centrally on the base region 17 and is again spaced away from the annular wall 18 by a flat annular region 20. The annular wall 18 of the second mould part 16 is arranged to form a close sliding fit inside the annular wall 13 of the first mould part 11. In this way the two mould parts may be fitted together as shown in Figure 1 forming a piston and cylinder device in which the two mould parts are slidable relative to each other in order to open or close the mould. The male mould surface 14 is arranged to face into the cup of the first mould part whereas the female mould surface 19 faces out of the cup of the second mould part so that when the two mould parts are fitted together as shown in Figure 1 a mould cavity 21 is formed between the male and female mould surfaces. The annular wall 13 of the first mould part 11 has an annular flange 22 at the end of the annular wall 13 remote from the base 12.

The wall members forming the male mould surface 14 and female mould surface 19 are sufficiently rigid that they do not substantially deflect under suction caused by shrinkage of monomer within the cavity 21 but can be deflected to keep in contact with shrinking monomer on application of a selected loading pressure which can be achieved by applying superatmospheric pressure to the mould halves in a pressurised oven or other pressure vessel. The female mould surface 19 is surrounded by a rigid shoulder 25 shown more clearly in Figure 2. The rigid shoulder 25 abuts the male mould surface 14 to form a reliable seal between the two mould surfaces and one which does not distort or deflect during the polymerisation operation when pressure is applied to the two mould halves.

The mould pieces shown in Figure 1 are in this example injection moulded from a suitable plastic material such as polypropylene.

In use liquid monomer is supplied into the concave surface of the female mould surface 19 while the surface is facing upwardly. The upper mould half is then closed downwardly onto the lower mould half as shown in Figure 1 until the male surface 14 touches the rigid shoulder 25 with the male mould half 11 uppermost. Any excess liquid monomer is squeezed out between the optical surfaces of the male and female mould parts

into the circular trough 23 so as to drain through the holes 24.

The assembly is then placed into a pressure vessel 26 as shown in Figure 3. Pressure inside the vessel is then increased by application of pressure from a source 27 of pressurised gas so that the two mould halves 11 and 16 are urged towards each other. The pressure in the vessel is preferably in the range of 0.2 to 1 bar above atmospheric. In particular the male and female mould surfaces 14 and 19 are urged towards each other by the applied pressure as indicated by arrows 30 and 31. The engagement force between the two mould halves is concentrated adjacent the shoulder 25 due to the relatively small surface area of engagement and thereby an effective seal is produced. This seal results in a clean edge to the lens and forms a barrier preventing escape of volatile components from the lens monomer in the mould cavity. Furthermore, this application of superatmospheric pressure inside the vessel 26 ensures that a satisfactory loading pressure is applied to the male and female mould surfaces 14 and 19 so that they are caused to deflect as the lens monomer shrinks in volume during polymerisation. In this way the optical surfaces of the male and female mould parts remain in contact with the monomer as it changes from liquid through gel to a solid. This avoids the problem of cavitation of the monomer as it shrinks. In this way the applied superatmospheric pressure creates a more effective seal and causes the mould surfaces to deflect and remain in contact with the monomer in a way which would not have been possible relying upon suction forces from the shrinkage of the monomer alone. The design, thickness and process control necessary in making the wall thicknesses for the male and female mould parts of this embodiment are much less sensitive as their resistance to movement does not need to be made to match the suction effect of the shrinking monomer. The resistance to movement of the mould parts is overcome by the applied superatmospheric pressure effect which may be easily controlled to achieve the desired deflection found necessary in use.

The optical surface of the male mould surface 14 has in this example been flame-treated, a process which improves the surface finish and raises the surface energy. This ensures that the polymerised lens remains in contact with the convex male mould part for subsequent processing. After treatment in the pressurised oven 26 shown in Figure 3, the mould is inverted and the two halves separated. The mould half 12 is removed so that as shown in Figure 4, the cast lens 32 remains on the male mould surface 16 in the cup member 13 below the level of the flange 14. In this way the cast lens is conveniently held with its outer optical

surface exposed for any further treatment steps. In the example shown in Figure 4 an optional printing head 33 is located above the cast lens so that any print treatment can be effected on the outer lens surface. The subsequent processing when the lens is held in the position shown in Figure 4 may additionally or alternatively include application of tint or colour to the front surface of the lens. The front surface of the lens 32 in this sense is the convex surface. As can be seen from Figure 4, the annular wall 13 of the mould part 11 extends upwardly to a height above the male mould surface 14 so that when the mould is opened the flange 22 at the upper end of the annular wall 13 lies above the lens 32 formed on the male mould surface. As the lens is held within the cup 13, the mould and lens can be accurately positioned without risk of damage which might occur if the lens were separate from the mould. The cup 13 provides an effective receptacle for extraction and/or hydration fluids which may serve to ease the lens non-traumatically from the optical mould surface. The mould and hence the lens can be handled efficiently by automatic processing equipment without risk of damage to the fragile lens. Furthermore the lens is suitably positioned in Figure 4 for laser drilling or other working.

After any surface treatment has been carried out, the lens 32 is hydrated while still held in the cup 13. This involves filling the trough region 15 in the cup with saline solution and requires no handling of the lens itself. As the problems of cavitation during monomer shrinkage and flash removal around the edge are avoided by the present invention, the process produces high quality lenses such that sampling inspection techniques can be applied in preference to repeated 100% lens inspection which is normal in the lens industry. This will result in lower cost lenses of at least equal quality to those produced in inspection intensive processes.

Finally a removable lid 34 is sealed onto the flange 22 of the mould part 11 so that the lens 32 and saline solution 35 are sealed within the package. Both the lid material and the seal have sufficiently good barrier properties to ensure that the packaging solution does not deteriorate over a substantial time. The materials selected for the package shown in Figure 5 are capable of withstanding conditions of sterilisation such as autoclaving.

In use, the lid 34 may be peeled away from the cup member holding the lens 32. When the lid is removed the saline solution may be poured out of the package and this may be done leaving the lens 32 held in position on the male mould surface 14. This is particularly advantageous in that the orientation of the lens is therefore predetermined in relation to the package position and makes it much simpler to extract the lens in a known orientation.

This avoids the need to tip the lens out of the container into an unknown orientation before picking up the lens for insertion into the eye. Furthermore the external face of the lens is facing upwardly in the package and consequently can be touched by hand without contaminating the lens before putting it into the eye.

The provision of the annular trough 15 around the male mould surface 14 also assists in removing the cast lens from the package in that it provides sufficient space around the lens to assist a user in getting hold of the lens in order to remove it from the package.

As already described, the lens may be subject to perforation by a plurality of fine holes by application of a laser beam such as a short wavelength excimer laser beam. Such laser beams break the chemical bonds and are able to perforate the cast lens without melting or causing flow or debris or other thermal effects. This process is known as photoablation decomposition. It is achieved by application of laser beams of short wavelength during short pulse durations. These form perforations which avoid any burr or ragged edge to the holes or grooves in the lens since they would cause unacceptable discomfort to the wearer of the lens. Figures 6, 7 and 8 show alternative perforation patterns which may be formed by use of an excimer laser. Such perforations may be beneficial in improving the oxygen transmission or permeability of the lens. The number and position of the holes or grooves will alter the oxygen flux, tearflow, durability and wettability characteristics of the final lens. The lens designer may therefore optimise the performance of the lens by suitable formation of perforations. In this example the holes 36 formed by the laser beam are each square holes approximately 150 microns in size. They may be used to cover the whole lens area stopping short of the periphery thereby maintaining the integrity of the lens edge as shown in Figure 6. Alternatively they may be formed in the central optical area 37 only as shown in Figure 7. Alternatively they may be formed in non-optical areas in an annular region 38 outside the central optical area but terminating short of the periphery as shown in Figure 8. The holes or grooves may be formed in the dry lens prior to hydration or alternatively in the wet lens after hydration.

The treatment stage prior to sealing the package as shown in Figure 5 may include dosing the lens with medication while the lens is held in the exposed position shown in Figure 4. By perforating the lens with an excimer laser as already described, the lens may act as a drug sponge in which the quantity of medication absorbed depends on the degree of perforation of the lens and the strength of the medication supplied to the cup

in which the lens is supported. The lens may be treated so as to form a controlled degree of perforation with absorption of a controlled drug quantity so that when sealed as in Figure 5 the package comprises a controlled dosed lens. In this way controlled doses of drugs may be prepackaged in the disposable lens format.

The formation of perforations as described in Figures 6, 7 and 8 by use of an excimer laser may be applied to cast contact lenses which are made by processes and apparatus different from that described with reference to Figures 1 to 5.

The present invention is advantageous in permitting the use of monomers which require ultraviolet curing or other non-thermal curing as well as monomers which are cured by heat treatment. It will be understood that when using heat treatment to effect curing, the mould surfaces develop a lower resistance to deflection during shrinkage of the monomer. However, when using monomers which do not require thermal curing, the mould surfaces will retain a higher resistance to deflection and the forces developed by monomer shrinkage alone would be insufficient to ensure that the mould surfaces remain in contact with the monomer as it shrinks. The use of the applied superatmospheric pressure may however be provided at a controlled extent above atmospheric pressure so as to be sufficient to deflect the mould surfaces and maintain them in contact with the monomer even when no heat treatment is applied as would be the case with ultraviolet curing.

The invention is not limited to the details of the foregoing example.

For instance, both the male and female mould surfaces may be flame polished in order to improve the surface finish on both sides of the lens. In order to release the lens from the mould and control which surface supports the lens after release, the mould may be partially opened to increase the cavity between the male and female surfaces and saline solution passed through the cavity by introducing the solution through one port 24 and exhausting the solution through another port 24 while the mould is tilted. The flow of saline solution will release the lens and by tilting the mould to an upright or inverted position before removal of the saline solution the released lens will come to rest and be supported on either the male surface or female surface as required.

## Claims

1. A method of cast moulding a contact lens comprising the steps of:

filling with monomer a mould cavity (21) of a mould, said cavity (21) being between relatively movable male (14) and female (19)

mould surfaces and said mould further comprising a rigid shoulder (25) for forming a peripheral seal between the two mould surfaces to close the cavity (21), at least one of the mould surfaces but not the shoulder (25) being flexible under a loading pressure;

closing said mould cavity (21) with monomer filling said cavity;

curing the monomer while applying a sealing pressure to provide a pressurised seal against the rigid shoulder (25) and a loading pressure to cause deflection of one of the mould surfaces to maintain the mould surfaces in contact with the lens as the monomer shrinks during polymerisation, characterised in that a superatmospheric pressure in a pressure vessel is applied to said mould, said superatmospheric pressure providing both said loading pressure and said sealing pressure, and is sufficient to cause the said pressurised seal formed by the rigid shoulder (25) to be maintained around the mould cavity throughout polymerisation to separate the contact lens from any flash, and the loading pressure to be sufficient to maintain the mould surfaces in contact with the lens as the monomer shrinks.

2. A method according to claim 1 wherein the male (14) and female (19) mould surfaces are formed on respective mould parts (11, 16) arranged to engage each other as a sliding piston and cylinder device, said application of a superatmospheric pressure being applied to both mould parts (11, 16) thereby urging the male (14) and female (19) mould surfaces towards each other.
3. A method according to either of claims 1 or 2 in which monomer is fed to said mould cavity (21) while the female mould surface (19) is facing upwardly, and inverting the mould so that on opening the mould said male surface (14) is facing upwardly.
4. A method according to claim 3 wherein on opening the mould the cast lens is supported on the male mould surface (14) surrounded by a cup member having an annular wall (13) projecting above the lens, hydrating fluid is supplied to the cup member to hydrate the lens while supported on the male surface (14) and a cover (34) is sealed onto the cup member above the lens to form a packaged lens in the cup member.
5. A method according to claim 4 in which the cover member (34) is sealed onto an upper edge of said annular wall (13).

6. A method according to any one of claims 1 to 5 wherein the male surface (14) is flame polished to assist in retaining the lens on the male surface (14) when the mould is opened.
7. A method according to any one of claims 1 to 5 wherein the female surface (19) is flame polished to assist in retaining the lens on the female surface (19) when the mould is opened.
8. A method according to any one of claims 1 to 5, 6 or 7 wherein after opening the mould the lens is held exposed on one mould surface (14, 19) and is subject to an additional treatment step on the exposed outer lens surface.
9. A method according to claim 8 wherein said additional treatment step comprises tinting, colouring or printing.
10. A method according to claim 8 wherein said additional treatment step comprises the formation of one or more holes (36) through the thickness of the lens by application of a short wavelength laser beam.
11. A method according to claim 10 wherein said beam is an excimer laser beam.
12. A method according to claim 10 or claim 11 in which a plurality of holes (36) are formed to form a controlled porosity of the lens.
13. A method according to claim 10 or claim 11 in which a plurality of holes (36) are formed to provide controlled durability of the lens.
14. A method according to claim 12 in which a controlled dosage of drug or other medical compound is introduced into the porosity formed by the hole formation.
15. A moulding apparatus for use in a method according to any one of the preceding claims, which moulding apparatus comprises a mould, said mould having a first mould part (11) having a male mould surface (14), a second mould part (16) having a female mould surface (19) and a rigid shoulder (25) which forms a peripheral seal between the two mould surfaces (14, 19) under sealing pressure, each of said mould parts (11, 16) having a base (12, 17) on which the respective mould surface (14, 19) is formed and an annular wall (13, 18) extending upwardly from the base (12, 17), the annular walls (13, 18) of the first (11) and second (16) mould parts being arranged to engage each other as a sliding fit whereby the two mould

parts (11, 16) may be moved as a piston and cylinder device to open and close the mould, at least one of the mould surfaces (14, 19) but not the shoulder (25) being flexible under a loading pressure, characterised in that the apparatus further comprises a pressure vessel in which said mould is received during the formation of a lens, said pressure vessel being arranged, in use, to apply superatmospheric pressure to said mould, said superatmospheric pressure providing both said loading pressure and said sealing pressure, and is sufficient to cause the said pressurised seal formed by the rigid shoulder (25) to be maintained around the mould cavity throughout polymerisation to separate the contact lens from any flash, and the loading pressure to be sufficient to maintain the mould surfaces in contact with the lens as the monomer shrinks.

16. A moulding apparatus according to claim 15 in which the male mould surface (14) is formed on the base (12) of said first mould part (11) spaced inwardly from the annular wall (13) of the first mould part (11) so as to provide a trough (15) within the annular wall (13) surrounding said male mould surface (14).
17. A moulding apparatus according to claim 16 in which the annular wall (13) on the first mould part (11) extends above said male mould surface (14).
18. A moulding apparatus according to claim 17 in which the annular wall (13) of said first mould part (11) is formed with a flange (22) at its upper end onto which a sealing cover (34) may be sealed.

#### Patentansprüche

1. Verfahren zum Gießen einer Kontaktlinse umfassend die folgenden Schritte:
  - Füllen eines Formhohlraums (21) eines Formwerkzeugs mit einem Monomer, wobei der Hohlraum (21) zwischen einer Patrizienoberfläche (14) und einer relativ dazu beweglichen Matrizenoberfläche (19) ausgebildet ist, und wobei das Formwerkzeug ferner eine starre Schulter (25) zum Formen einer randseitigen Dichtung zwischen den beiden Formwerkzeugoberflächen zum Schließen des Hohlraums (21) aufweist, wobei zumindest eine der Formwerkzeugoberflächen, nicht jedoch die Schulter (25), unter Belastungsdruck flexibel ist;

- Schließen des Formhohlraums (21), wobei ein Monomer den Hohlraum ausfüllt;
- Härten des Monomers während ein Dichtungsdruck ausgeübt wird, um eine unter Druck stehende Abdichtung an der starren Schulter (25) bereitzustellen sowie Ausüben eines Belastungsdrucks, um eine Biegung einer der Formwerkzeugoberflächen zu verursachen, um die Formwerkzeugoberflächen in Kontakt mit der Linse zu halten, wenn das Monomer während der Polymerisation schrumpft, dadurch gekennzeichnet, daß ein superatmosphärischer Druck in einem Druckbehälter auf das Formwerkzeug ausgeübt wird, wobei der superatmosphärische Druck sowohl den Belastungsdruck als auch den Dichtungsdruck bereitstellt, und ausreichend ist, um die unter Druck stehende, durch die starre Schulter (25) gebildete Abdichtung während der Polymerisation um den Formhohlraum aufrechtzuerhalten, um die Linse von jedwedem Gußgrat zu trennen, wobei der Belastungsdruck ausreichend ist, um die Formwerkzeugoberflächen in Kontakt mit der Linse zu halten, während das Monomer schrumpft.

2. Verfahren nach Anspruch 1, bei dem die Patrizien- (14) und die Matrizenoberfläche (19), die auf entsprechenden Formwerkzeugteilen (11, 16) ausgeformt sind, so angeordnet sind, daß sie wie ein Schiebekolben und eine Zylindervorrichtung miteinander in Eingriff kommen, wobei durch die Anwendung von superatmosphärischem Druck, der auf beide Formwerkzeugteile (11, 16) ausgeübt wird, die Patrizien- (14) und die Matrizenoberfläche (19) zusammengepreßt werden.
3. Verfahren nach einem der Ansprüche 1 oder 2, bei dem ein Monomer in den Formhohlraum (21) eingespeist wird, während die Matrizenoberfläche (19) nach oben weist, und das Formwerkzeug umgedreht wird, so daß beim Öffnen des Formwerkzeugs die Patrizienoberfläche (14) nach oben weist.
4. Verfahren nach Anspruch 3, bei dem beim Öffnen des Formwerkzeugs die gegossene Linse auf der Patrizienoberfläche (14) aufgenommen ist und von einem Schalenteil mit einer ringförmigen, über die Linse herausragenden Wand (13) umgeben ist, dem Schalenteil ein hydratisierendes Fluid zugeführt wird, um die Linse zu hydratisieren, während sie auf der Patrizienoberfläche (14) auf-

- nommen ist und eine Abdeckung (34) auf dem Schalenteil über der Linse abgedichtet wird, um eine verpackte Linse in dem Schalenteil zu bilden.
5. Verfahren nach Anspruch 4, bei dem das Abdeckteil (34) auf einer oberen Kante der ringförmigen Wand (13) abgedichtet wird.
  6. Verfahren nach einem der Ansprüche 1 bis 5, bei dem die Patrizienoberfläche (14) flammenpoliert ist, um das Zurückhalten der Linse auf der Patrizienoberfläche (14) beim Öffnen des Formwerkzeugs zu unterstützen.
  7. Verfahren nach einem der Ansprüche 1 bis 5, bei dem die Matrizenoberfläche (19) flammenpoliert ist, um das Zurückhalten der Linse auf der Matrizenoberfläche (19) beim Öffnen des Formwerkzeugs zu unterstützen.
  8. Verfahren nach einem der Ansprüche 1 bis 5, 6 oder 7, bei dem nach dem Öffnen des Formwerkzeugs die Linse freiliegend auf einer Formwerkzeugo-berfläche (14, 19) gehalten und einem zusätz-lichen Behandlungsschritt an der freiliegenden äußeren Linsenoberfläche unterzogen wird.
  9. Verfahren nach Anspruch 8, bei dem der zusätzliche Behandlungsschritt Tönen, Färben oder Bedrucken umfaßt.
  10. Verfahren nach Anspruch 8, bei dem der zusätzliche Behandlungsschritt die Bildung eines oder mehrerer Löcher (36) durch die Dicke der Linse durch Anwendung eines kurzwelligen Laserstrahls umfaßt.
  11. Verfahren nach Anspruch 10, bei dem der Strahl ein Excimer-Laserstrahl ist.
  12. Verfahren nach Anspruch 10 oder 11, bei dem eine Mehrzahl von Löchern (36) gebil-det wird, um eine gesteuerte Porosität der Linse zu bilden.
  13. Verfahren nach Anspruch 10 oder 11, bei dem eine Mehrzahl von Löchern (36) gebil-det wird, um eine gesteuerte Stabilität der Lin-se bereitzustellen.
  14. Verfahren nach Anspruch 12, bei dem eine gesteuerte Dosis eines Arznei-mittels oder einer anderen medizinischen Ver-bindung in die durch die Löcherbildung ge-formte Porosität eingeführt wird.
  15. Formvorrichtung zur Verwendung in einem erfindungsgemäßen Verfahren nach einem der vorhergehenden Ansprüche, wobei die Formvorrichtung ein Formwerkzeug umfaßt, wobei das Formwerkzeug ein erstes Formwerkzeugteil (11) mit einer Patrizienober-fläche (14), ein zweites Formwerkzeugteil (16) mit einer Matrizenoberfläche (19) und eine starre Schulter (25), die eine randseitige Dich-tung zwischen den beiden Formwerkzeugo-berflächen (14, 19) unter Dichtungsdruck bildet, aufweist, wobei jedes der Formwerkzeuge (11, 16) eine Basis (12, 17) aufweist, auf der die entsprechende Formwerkzeugo-berfläche (14, 19) ausgebildet ist und sich eine ringförmige Wand (13, 18) von der Basis (12, 17) nach oben erstreckt, wobei die ringförmigen Wände (13, 18) des ersten (11) und zweiten (16) Formwerkzeugteils so angeordnet sind, daß sie in Gleitpassung miteinander in Eingriff kom-men, wobei die beiden Formwerkzeugteile (11, 16) wie eine Kolben- und Zylindervorrichtung bewegt werden können, um das Formwerk-zeug zu öffnen und zu schließen, wobei zumin-dest eine der Formwerkzeugo-berflächen (14, 19), nicht jedoch die Schulter (25), unter Bela-stungsdruck flexibel ist, dadurch gekennzeichnet, daß die Vorrichtung ferner einen Druckbehälter um-faßt, in dem das Formwerkzeug während der Herstellung einer Linse aufgenommen wird, wobei der Druckbehälter im Betrieb so ausge-legt ist, daß auf das Formwerkzeug superatmo-sphärischer Druck ausgeübt wird, wobei der superatmosphärische Druck sowohl den Bela-stungsdruck als auch den Dichtungsdruck be-reitstellt und ausreichend ist, um zu verursa-chen, daß die unter Druck stehende, durch die starre Schulter (25) gebildete Abdichtung wäh-rend der Polymerisation um den Formhohl-raum aufrechterhalten wird, um die Kontaktlin-se von jedwedem Gußgrat zu trennen, wobei der Belastungsdruck ausreichend ist, um die Formwerkzeugo-berflächen in Kontakt mit der Linse zu halten, wenn das Monomer schrumpft.
  16. Formvorrichtung nach Anspruch 15, bei dem die Patrizienoberfläche (14) auf der Basis (12) des ersten Formwerkzeugteils (11) ausgeformt und nach innen von der ringförmigen Wand (13) des ersten Formwerkzeugteils (11) beabstandet ist, um einen Durchgang (15) innerhalb der ringförmigen Wand (13), die die Patrizienoberfläche (14) umgibt, bereitzustellen.
  17. Formvorrichtung nach Anspruch 16, bei dem sich die ringförmige Wand (13) auf

dem ersten Formwerkzeugteil (11) über die Patrizienoberfläche (14) hinaus erstreckt.

18. Formvorrichtung nach Anspruch 17, bei dem die ringförmige Wand (13) des ersten Formwerkzeugteils (11) mit einem Flansch (22) an ihrem oberen Ende, auf dem die dichtende Abdeckung (34) abgedichtet werden kann, ausgeformt ist.

#### Revendications

1. Procédé de moulage d'une lentille de contact, comprenant les étapes consistant à:
  - remplir de monomère une cavité de moulage (21) d'un moule, ladite cavité (21) étant entre des surfaces mâle (14) et femelle (19) de moule mobiles l'une par rapport à l'autre et ledit moule comportant en outre un épaulement rigide (25) pour former entre les deux surfaces de moule un élément d'étanchéité périphérique pour fermer la cavité (21), au moins une des surfaces de moule, mais non l'épaulement (25), pouvant fléchir sous une pression de charge;
  - fermer ladite cavité (21) de moule, ladite cavité étant remplie de monomère;
  - polymériser le monomère tout appliquant une pression d'étanchéité pour réaliser un joint d'étanchéité comprimé contre l'épaulement rigide (25) et une pression de charge pour faire fléchir une des surfaces de moule afin de maintenir les surfaces de moule au contact de la lentille à mesure que le monomère se contracte pendant la polymérisation, caractérisé en ce qu'une pression supérieure à la pression atmosphérique dans un récipient sous pression est appliquée audit moule, ladite pression supérieure à la pression atmosphérique réalisant à la fois ladite pression de charge et ladite pression d'étanchéité, et est suffisante pour amener ledit joint d'étanchéité comprimé formé par l'épaulement rigide (25) à être maintenu autour de la cavité du moule tout au long de la polymérisation pour séparer la lentille de contact de toute bavure éventuelle, et la pression de charge à être suffisante pour maintenir les surfaces de moule au contact de la lentille à mesure que le monomère se contracte.
2. Procédé selon la revendication 1, dans lequel les surfaces mâle (14) et femelle (19) de moule sont formées sur des parties respectives (11, 16) de moule conçues pour venir l'une contre l'autre à la manière d'un dispositif à piston coulissant et cylindre, ladite application d'une pression supérieure à la pression atmos-

phérique étant effectuée sur les deux parties (11, 16) de moule en poussant de ce fait les surfaces mâle (14) et femelle (19) de moule l'une vers l'autre.

3. Procédé selon l'une ou l'autre des revendications 1 ou 2, dans lequel le monomère est introduit dans ladite cavité (21) de moule pendant que la surface femelle (19) de moule est orientée vers le haut, et le moule est retourné de façon qu'à l'ouverture du moule ladite surface mâle (14) soit orientée vers le haut.
4. Procédé selon la revendication 3, dans lequel, à l'ouverture du moule, la lentille moulée repose sur la surface mâle (14) de moule entourée par un élément formant cuvette ayant une paroi annulaire (13) qui fait saillie au-dessus de la lentille, un fluide hydratant est fourni à l'élément formant cuvette pour hydrater la lentille pendant qu'elle repose sur la surface mâle (14) et un couvercle (34) est hermétiquement fermé sur l'élément formant cuvette au-dessus de la lentille pour former dans la cuvette une lentille conditionnée.
5. Procédé selon la revendication 4, dans lequel le couvercle (34) est hermétiquement fermé sur le bord supérieur de ladite paroi annulaire (13).
6. Procédé selon l'une quelconque des revendications 1 à 5, dans lequel la surface mâle (14) est polie à la flamme pour faciliter le maintien de la lentille sur la surface mâle (14) lors de l'ouverture du moule.
7. Procédé selon l'une quelconque des revendications 1 à 5, dans lequel la surface femelle (19) est polie à la flamme pour faciliter le maintien de la lentille sur la surface femelle (19) lors de l'ouverture du moule.
8. Procédé selon l'une quelconque des revendications 1 à 5, 6 ou 7, dans lequel, après l'ouverture du moule, la lentille reste exposée sur une surface (14, 19) de moule et est soumise à un traitement supplémentaire sur la surface extérieure exposée de la lentille.
9. Procédé selon la revendication 8, dans lequel ledit traitement supplémentaire consiste à teinter, colorer ou imprimer la surface de la lentille.
10. Procédé selon la revendication 8, dans lequel ledit traitement supplémentaire comporte la formation d'un ou plusieurs trous (36) dans

l'épaisseur de la lentille par application d'un faisceau laser à courte longueur d'onde.

11. Procédé selon la revendication 10, dans lequel ledit faisceau est un faisceau laser excimer. 5
12. Procédé selon la revendication 10 ou la revendication 11, dans lequel une pluralité de trous (36) sont formés pour obtenir une porosité voulue de la lentille. 10
13. Procédé selon la revendication 10 ou la revendication 11, dans lequel une pluralité de trous sont formés pour obtenir une durabilité voulue de la lentille. 15
14. Procédé selon la revendication 12, dans lequel une dose voulue de médicament ou autre composition médicamenteuse est introduite dans les pores obtenus par la formation des trous. 20
15. Dispositif de moulage utilisable dans un procédé selon l'une quelconque des revendications précédentes, lequel dispositif de moulage comporte un moule, ledit moule possédant une première partie (11) de moule ayant une surface mâle (14) de moule, une seconde partie (16) de moule ayant une surface femelle (19) de moule et un épaulement rigide (25) qui constitue un joint d'étanchéité périphérique entre les deux surfaces (14, 19) de moule sous l'effet d'une pression d'étanchéité, chacune desdites parties (11, 16) de moule ayant une base (12, 17) sur laquelle est formée la surface respective (14, 19) de moule et une paroi annulaire (13, 18) qui s'étend vers le haut depuis la base (12, 17), les parois annulaires (13, 18) des première (11) et seconde (16) parties de moule étant conçues pour venir l'une contre l'autre par ajustement glissant, grâce à quoi les deux parties (11, 16) de moule peuvent se déplacer comme un dispositif à piston et cylindre pour ouvrir et fermer le moule, au moins une des surfaces (14, 19) de moule, mais non l'épaulement (25), pouvant fléchir sous une pression de charge, caractérisé en ce que le dispositif comporte en outre un récipient sous pression dans lequel ledit moule est logé pendant la formation d'une lentille, ledit récipient sous pression étant conçu pour appliquer audit moule, en fonctionnement, une pression supérieure à la pression atmosphérique, ladite pression supérieure à la pression atmosphérique réalisant à la fois ladite pression de charge et ladite pression d'étanchéité, et étant suffisante pour amener ledit joint comprimé formé par l'épaulement rigide 25 30 35 40 45 50 55

(25) à être maintenu autour de la cavité du moule pendant toute la polymérisation pour séparer la lentille de contact de toute bavure éventuelle, et la pression de charge à être suffisante pour maintenir les surfaces de moule au contact de la lentille à mesure que le monomère se contracte.

16. Dispositif de moulage selon la revendication 15, dans lequel la surface mâle (14) de moule est formée sur la base (12) de ladite première partie (11) de moule espacée, vers l'intérieur, de la paroi annulaire (13) de la première partie (11) de moule afin de réaliser un chéneau (15) dans la paroi annulaire (13) entourant ladite surface mâle (14) de moule.
17. Dispositif de moulage selon la revendication 16, dans lequel la paroi annulaire (13) sur la première partie (11) de moule s'étend au-dessus de ladite surface mâle (14) de moule.
18. Dispositif de moulage selon la revendication 17, dans lequel la paroi annulaire (13) de ladite première partie (11) de moule comporte à son extrémité supérieure un rebord (22) sur lequel peut être fixé un couvercle de fermeture hermétique (34).
